

The Bohr Effect

Or how to get Heme to pick up and drop off oxygen

Marguerite Butler

Zool 430

RIGH
T

The Bohr effect

Explains how high $[\text{CO}_2]$ helps hemoglobin release O_2 in tissues that need it

O_2 Concentration

O_2 Affinity

O_2 -loving

O_2 -meh

pH

Hb-Oxygen Dissociation Curve

Hemoglobin binds O_2 reversibly

Hemoglobin

The oxygen shuttle.
Picks up O_2 at the lungs and dumps O_2 at the tissues.

Hemoglobin

it's made up of 4 separately-made protein chains

2 α -globin chains

2 β -globin chains

it has 4 heme groups that hold iron & help hemoglobin bind & transport oxygen

the **Bohr effect** involves interactions between the chains that happen here

these interactions can only occur at low pH, like can be caused by high CO₂

Heme Binds Oxygen Reversibly

- Heme binds O_2 via Fe^{2+}
- 4 hemes \Rightarrow 4 O_2 per hemoglobin
- O_2 stabilized by H-bonds with Histidine residues in globin

Subunits Bind O₂ Cooperatively

Hemoglobin has 4 subunits

Hemoglobin
is an O₂
shuttle

Reversible, All-or-None

Low Affinity
“O₂ Grumpy”

High Affinity
“O₂ Sticky”
*Doesn't need to
meet a lot of O₂*

Subunits Bind O₂ Cooperatively

"O₂-grumpy" "O₂-sticky"

4 subunits

If one
subunit
binds O₂

All 4 change
affinity
"O₂-sticky"

Reversible, All-or-None

What changes hemoglobin's mood?

Taut
low oxygen affinity
unload

Relaxed
high oxygen affinity
load

low-pH-dependent salt bridges stabilize the taut form

T

PDB 2hhb

PDB 1hho

R

in the taut form, hemes are in a harder place for oxygen to hang out. oxygen binding kinda pulls on the heme (& attached protein) - this helps promote the other sites to bind oxygen too, giving you positive cooperativity, so that

this

is much easier than

What changes hemoglobin's mood?

In the T form, salt bridges (ionic bonds) form between the chains

At low pH
 \Rightarrow lots H^+

His- residue can form salt bridge

Blocking O_2 binding

In the R form, His is deprotonated, so it can't form that His-positioning salt bridge

His- deprotonated, blocking salt bridge

O_2 can bind

shifting the oxyhemoglobin dissociation curve

higher affinity for oxygen

lower affinity for oxygen

they're more likely to stick each time they meet, so they don't need to meet as much in order to get the same amount of binding.

each time oxygen & hemoglobin meet they have a lower probability of sticking. So they need to meet more in order to get the same amount of binding.

The Bohr effect

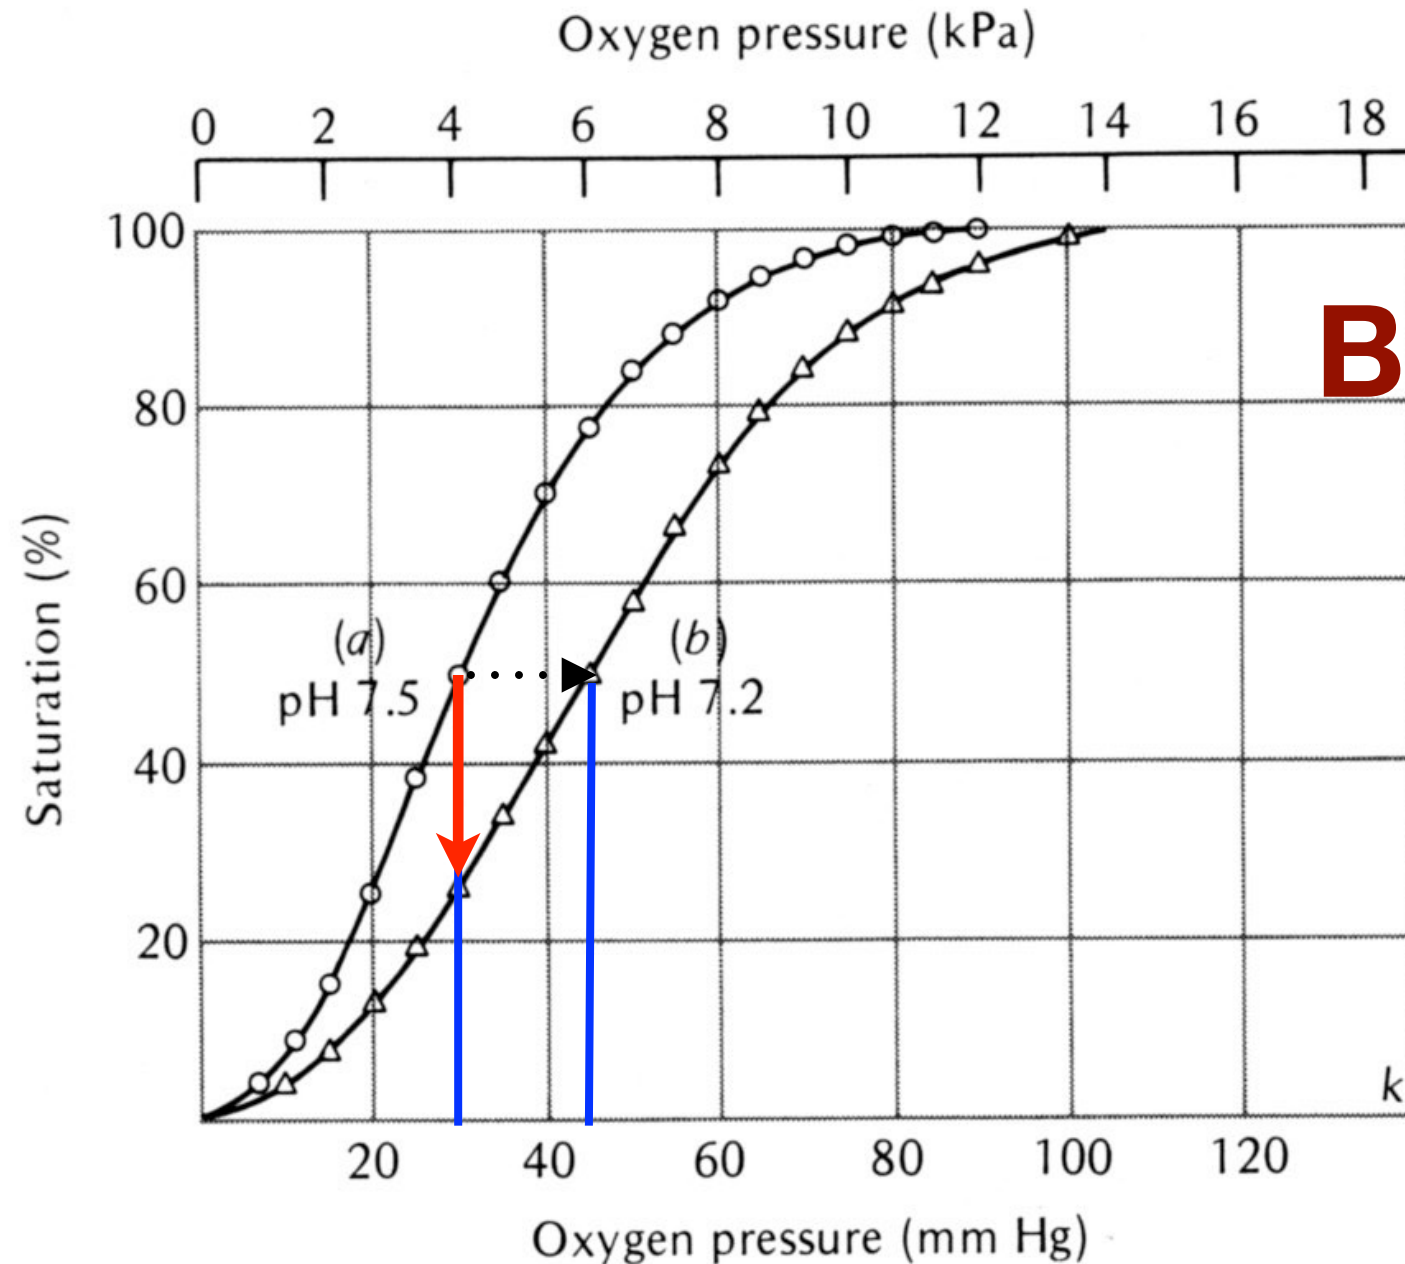

Why CO_2 and pH?

$$pH = \log_{10} \left(\frac{1}{[H^+]} \right)$$

CO_2 Acidifies blood
Lowers pH!

Subunits Bind O₂ Cooperatively

Bohr-Shift

CO₂ and **pH**
enhances
dumping of
oxygen at the
tissues

Reversible, All-or-None

Subunits Bind O₂ Cooperatively

Example:

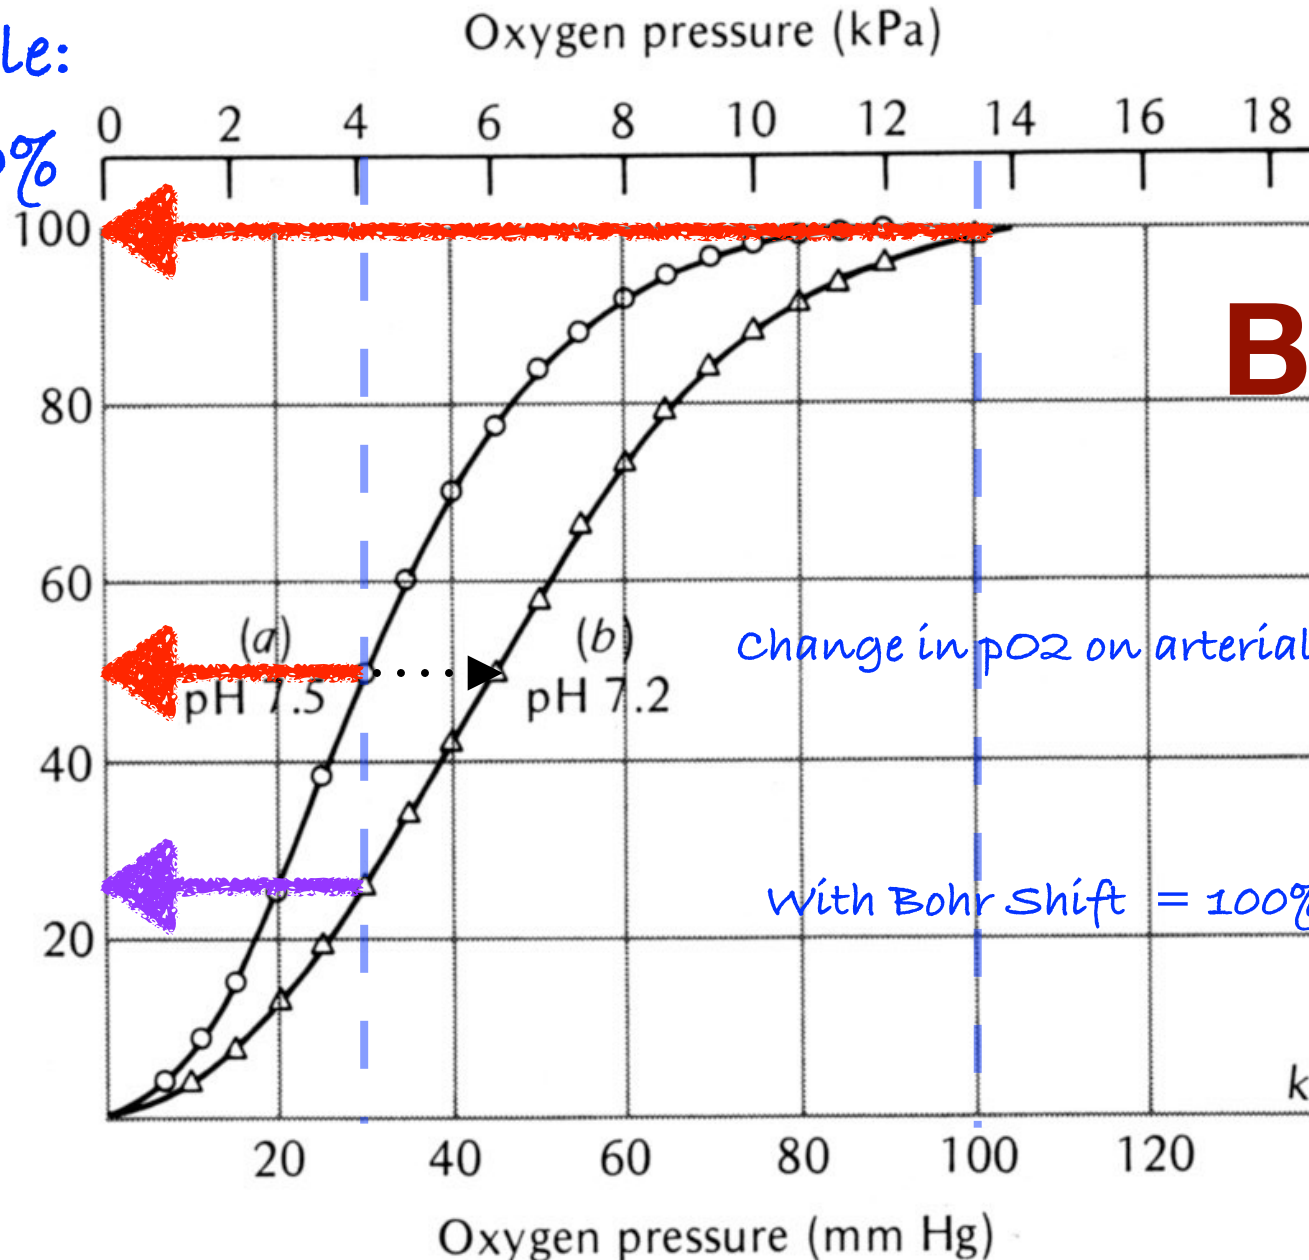

Hb 100%

Hb

50%

Hb

25%

Bohr-Shift

Change in pO₂ on arterial system = 100% - 50%
= 50% delivery

With Bohr Shift = 100% - 25% = 75% delivery

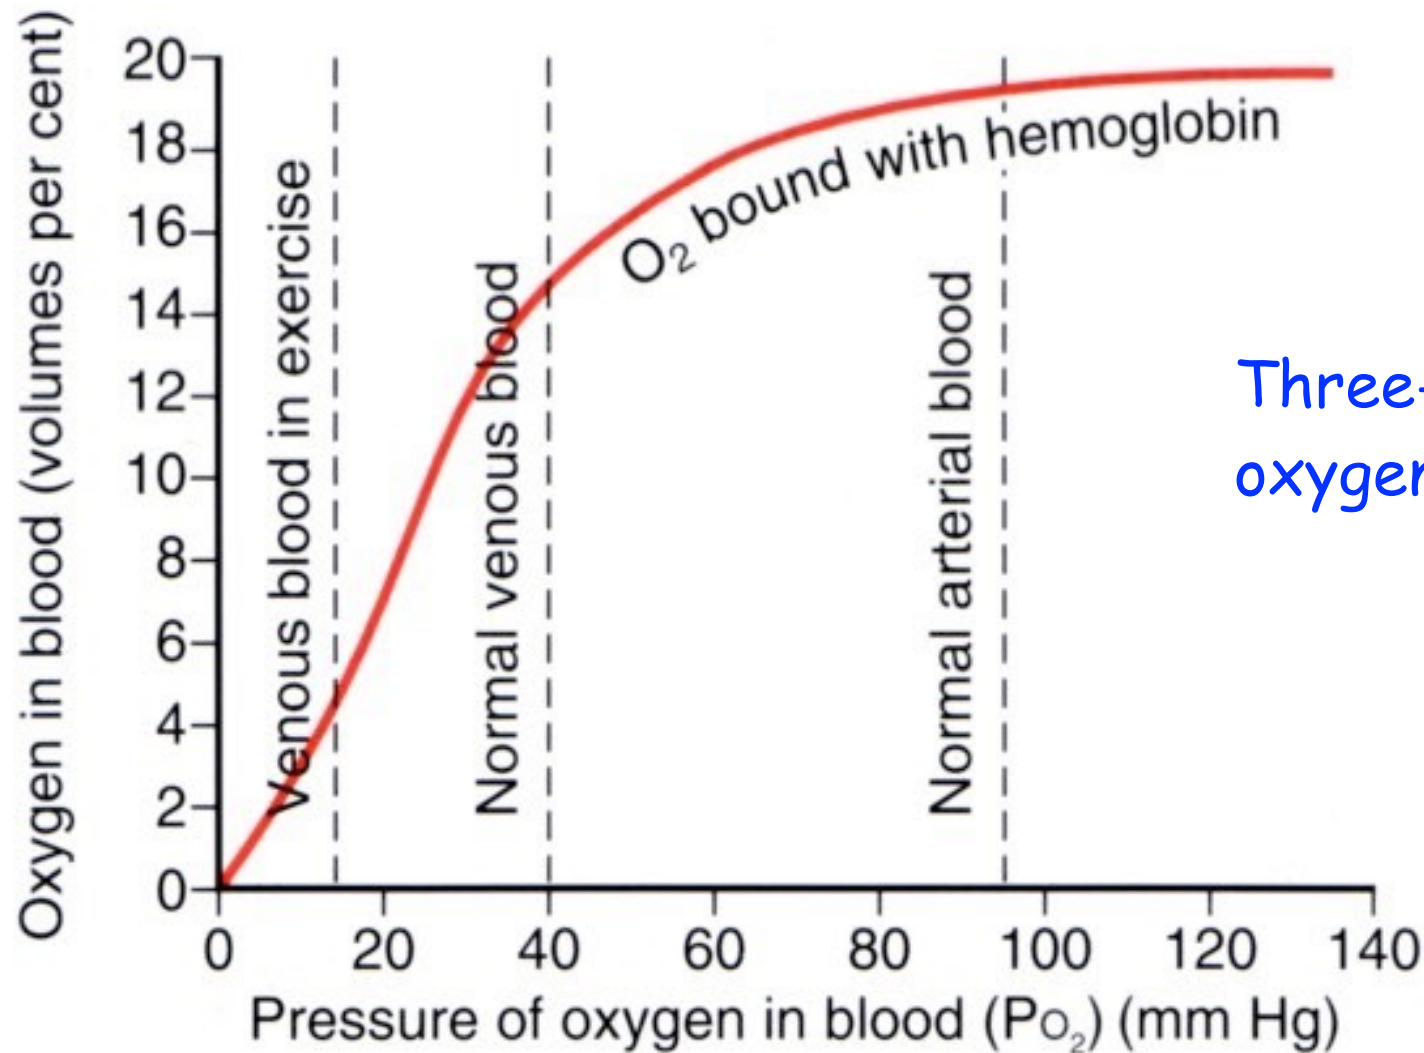

Reversible, All-or-None

Bohr Effect enhances O₂ delivery to tissues

- Arterial blood has lower CO₂ and higher pH than tissues
- Venous blood has higher CO₂ and lower pH than tissues
- Hence net O₂ delivery from arterial to venous blood enhanced by Bohr effect beyond expectations due to PO₂ alone.

Effect of Exercise on Oxygen Delivery

Three-fold increase in oxygen delivery.

Respiratory Pigments

Myoglobin: Monomer

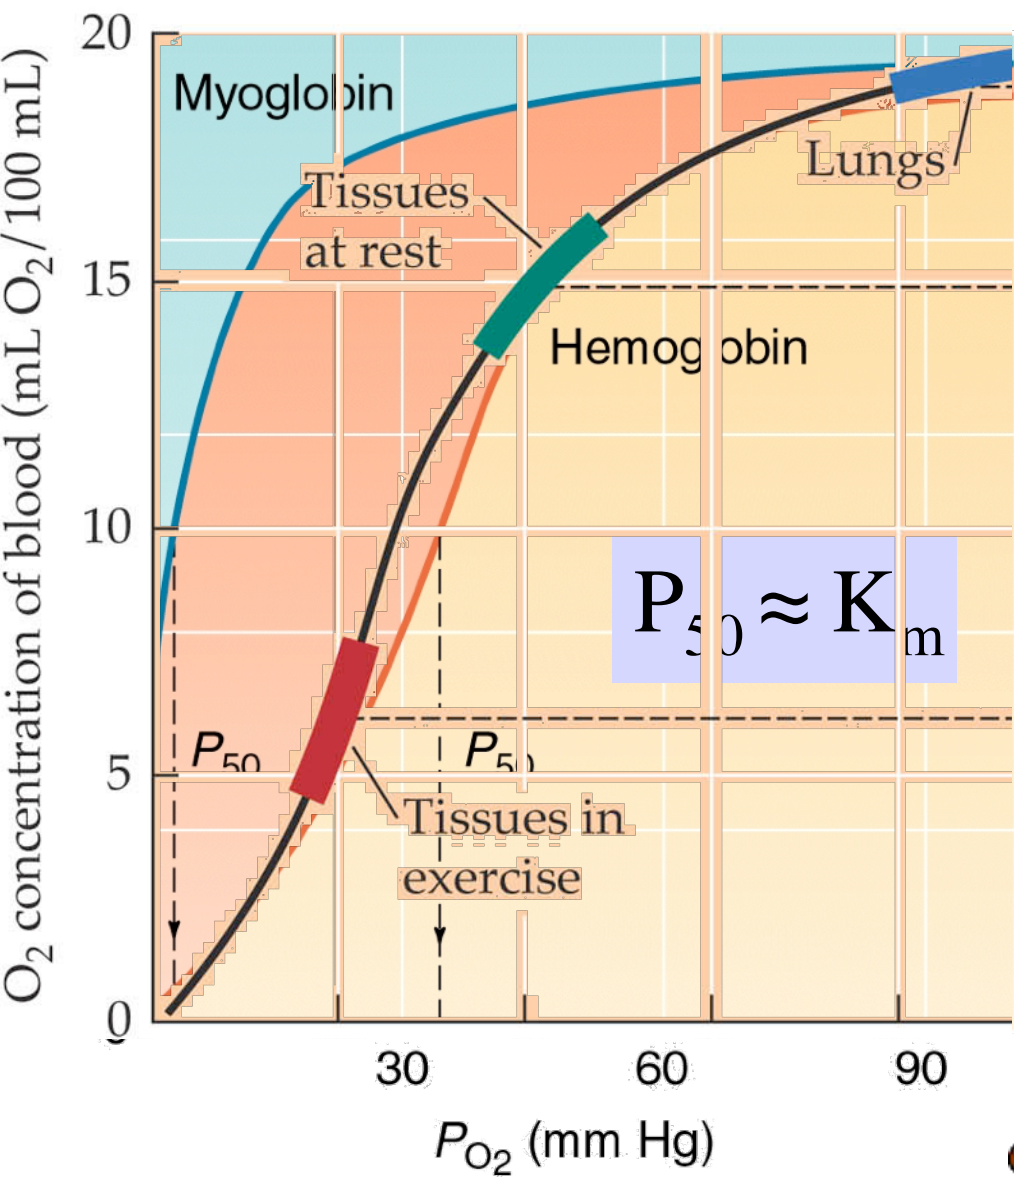

within muscle cells

Hemoglobin: Tetramer Heterodimer: ($\alpha_1\beta_1$ & $\alpha_2\beta_2$)

within red blood cells

Oxygen binding of Myoglobin (Mb) and Hemoglobin (Hb)

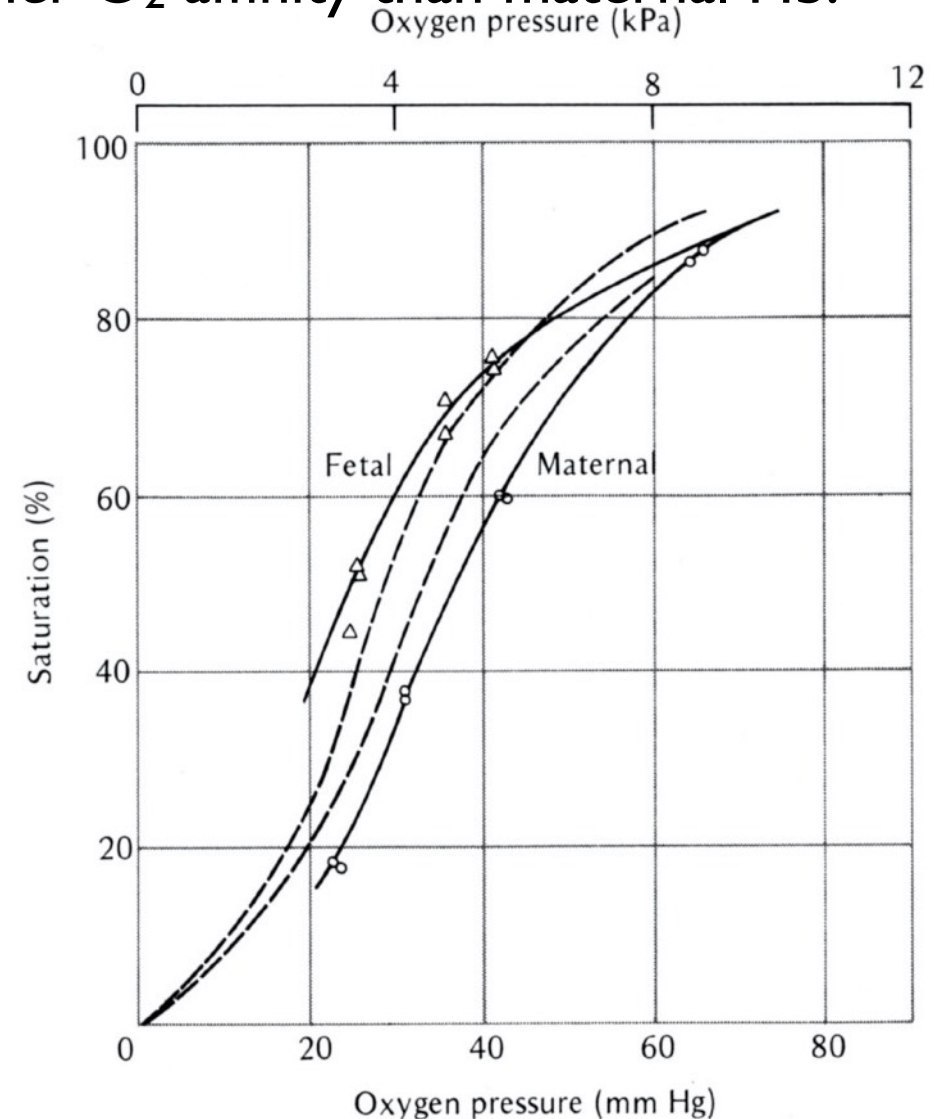

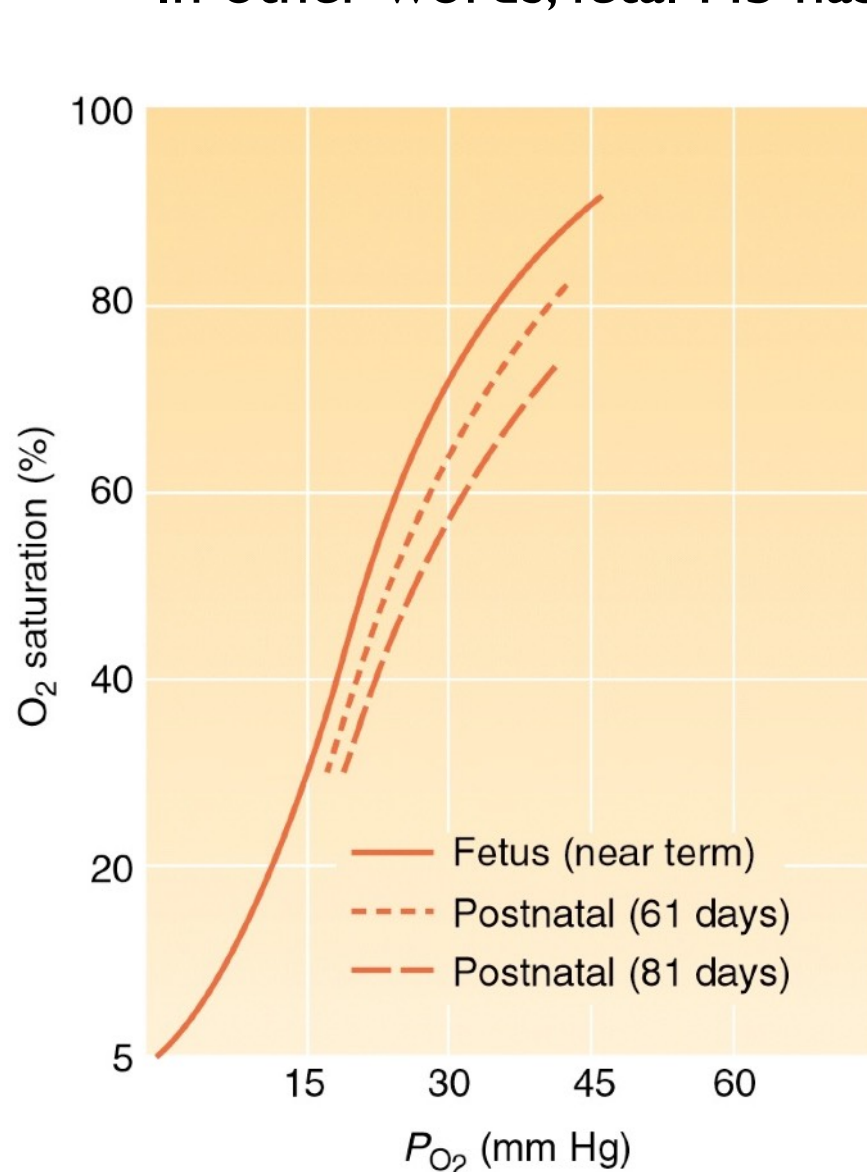

- Mb has higher affinity (lower P₅₀) than Hb
- Hb binds O₂ cooperatively
- Functional Result:
O₂ always transferred from Hb to Mb at tissues

Fetal vs. Maternal Blood

- Hb subunits change with development in mammals
 - Fetal Hbs have lower P_{50} which is essential in O_2 transfer from mother to fetus
 - In other words, fetal Hb has higher O_2 affinity than maternal Hb.

Developmental changes in Hb subunits and P₅₀

- Fetal O₂ affinity determined by globin subunit type

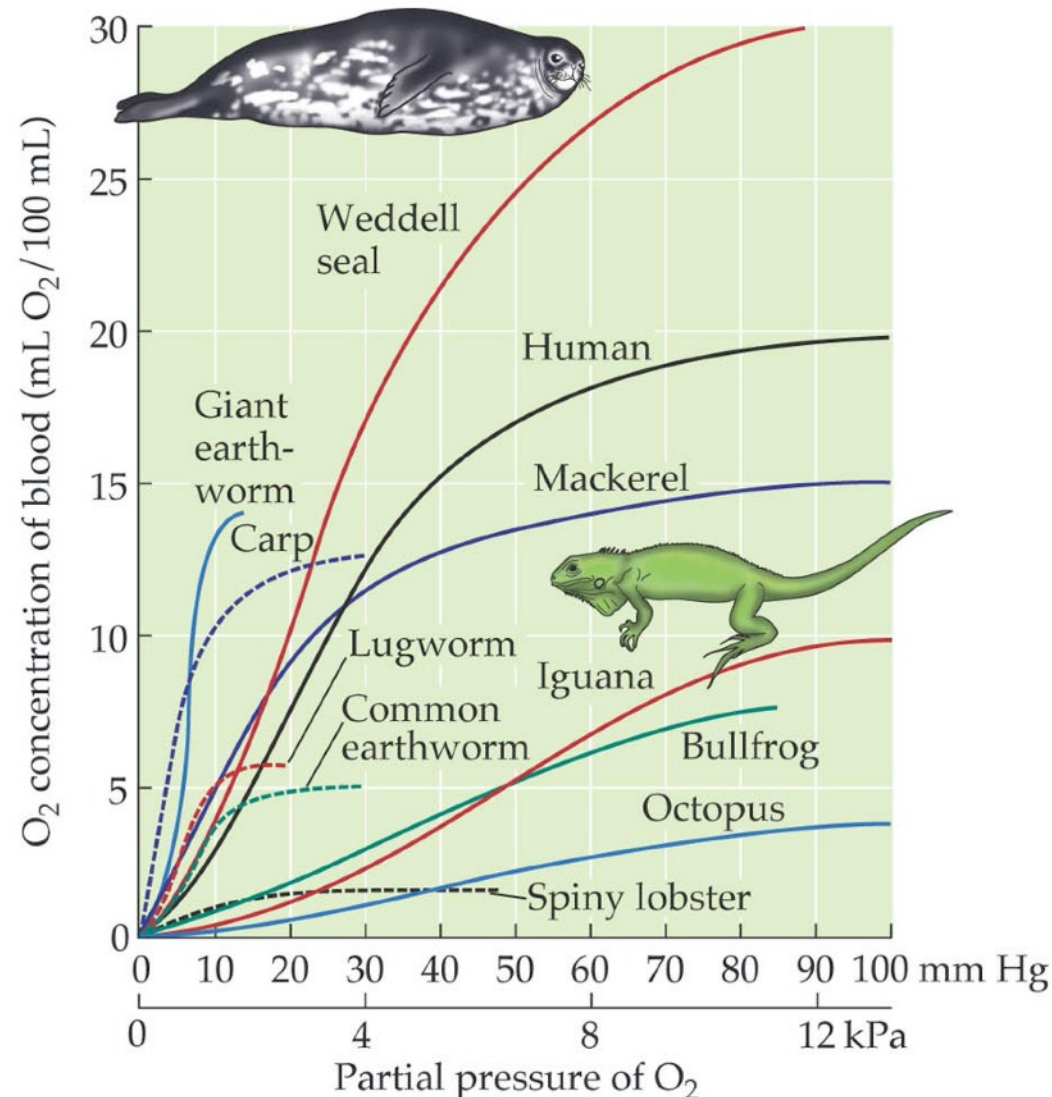

4 globin subunits

1 globin subunits

Huge interspecific variation in oxygen affinity of blood

- Adaptation to
 - Temperature
 - Hypoxia
 - Activity
- Evolutionary factors
 - Respiratory protein class

Interspecific variation of Hb function

pO_2 of Mammalian Lung = 100 mm Hg (13kPa)

say O_2 is unloaded to tissues at 50% saturation

Increasing temperature increases Hb P_{50}

- Metabolic activity produces heat as a by-product
- Active muscles have higher temperatures than incoming blood
 - Thus, warmer temps will favor O_2 unloading

Ventilation can alter blood chemistry!

pH, Bicarb and P_{CO_2} in human plasma usually w/ in narrow limits

hyper- and hypo-ventilation alters blood CO_2 levels. THEN plasma pH and bicarb are altered beyond the normal range

CO_2 levels are also affected by diet (R_q)

Acclimation of Hb function

Eels acclimated to hypoxic conditions

Trout acclimated to different temperatures

(b) Venous O₂ partial pressure monitored remotely with cutting-edge technology

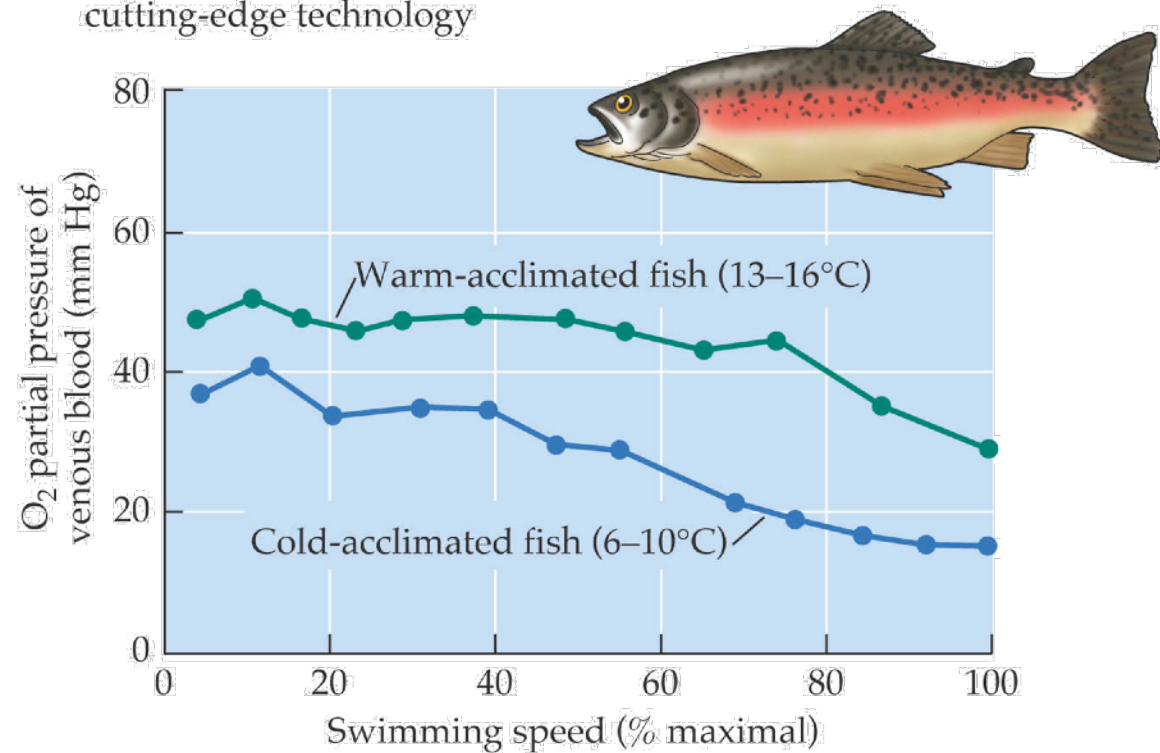

TABLE 2.2 Common respiratory pigments and examples of their occurrence in animals.

Pigment	Description	Molecular weight	Occurrence in animals
Hemocyanin	Copper-containing protein, carried in solution	300 000–9 000 000	Molluscs: chitons, cephalopods, prosobranch and pulmonate gastropods, not lamellibranchs Arthropods, crabs, lobsters Arachnomorphs: <i>Limulus</i> , <i>Euscorpius</i>
Hemerythrin	Iron-containing protein, always in cells, nonporphyrin structure	108 000	Sipunculids: all species examined Polychaetes: <i>Magelona</i> Priapulids: <i>Halicryptus</i> , <i>Priapululus</i> Brachiopods: <i>Lingula</i>
Chlorocruorin	Iron-porphyrin protein, carried in solution	2 750 000	Restricted to four families of Polychaetes: Sabelliidae, Serpulidae, Chlorhaemidae, Ampharetidae; prosthetic group alone found in starfish (<i>Luidia</i> , <i>Astropecten</i>)
Hemoglobin	Iron-porphyrin protein, carried in solution or in cells; most extensively distributed pigment	17 000–3 000 000	Vertebrates: almost all, except leptocephalus larvae and some Antarctic fish (<i>Chaenichthys</i>) Echinoderms: sea cucumbers Molluscs: <i>Planorbis</i> , Pismo clam (<i>Tivela</i>) Arthropods: insects (<i>Chironomus</i> , <i>Gastrophilus</i>); crustacea (<i>Daphnia</i> , <i>Artemia</i>) Annelids: <i>Lumbricus</i> , <i>Tubifex</i> , <i>Arenicola</i> , <i>Spirorbis</i> (some species have hemoglobin, some chlorocruorin, others no blood pigment), <i>Serpula</i> (both hemoglobin and chlorocruorin) Nematodes: <i>Ascaris</i> Flatworms: parasitic trematodes Protozoa: <i>Paramecium</i> , <i>Tetrahymena</i> Plants: yeasts, <i>Neurospora</i> , root nodules of leguminous plants (clover, alfalfa)

Schmidt-Neilsen (1997)

Evolutionary loss of respiratory proteins

- All fishes have respiratory pigments, except one:
The Antarctic Icefish, *Chaenocephalus aceratus*

- Functional consequences - much less O_2 in blood
 - Although cold temp does incr. solubility
- Icefish adaptations:
 - Increased blood volume
 - Increased cardiac output
 - Low metabolic rate

Root Effect

Regulation of Buoyancy in Fishes with Swim Bladders/Lungs

“Flesh” is slightly denser than water, so without generating any lift, a fish will sink. Most living fishes (except chondrichthyans) have swim bladders or lungs to regulate buoyancy (by controlling the amount of gas inside).

Neutral buoyancy = having the same average density as water so that animal does not sink or float in the water column.

Root Effect

under the root effect, Hb unloads O_2

Root Effect

The swim bladder challenge: working against huge O_2 gradients

- Plot assumes no change in swimbladder gas content with depth
- Result: must move O_2 into swim bladder against a pressure gradient of many atmospheres at depth

Root Effect

How to get O_2 into swim bladder against a high pressure?

say swimbladder contains O_2 at high pressure (100atm for 1000m depth), but arterial O_2 tension is no more than 0.2 atm.

Gas secretion produces lactic acid

Lactic acid enters blood and reduces affinity for O_2 (Root effect)

Drives O_2 off the hemoglobin

Countercurrent flow tends to concentrate lactic acid and O_2 concentration effects at the rete capillaries/gas gland interface

Eventually, O_2 able to diffuse into swim bladder

Root Effect

Root shifts are key

- Gas Gland:
 - Glycolysis
 - H^+ production
 - Pentose phosphate
 - CO_2 production
 - Activity decreases pH and increases ionic concentration
 - Root-off shift
 - lower O_2 solubility
- Rete:
 - counter current gas exchanger for CO_2
 - Drives CO_2 into arterial blood causing Root-off

The Bohr Effect
